## Escape the Nuke Worked Solution

### Question 1

First let us calculate how long it will take to run up 500 metres of stairs at 10 km/hr. Let's convert the speed into m/s:

$$\text{Speed} = 10 \text{ km/hr} \times 1000 \text{ m/km} / 3600 \text{ s/hr}$$

$$\text{Speed} = 2.78 \text{ m/s} \quad (1 \text{ mark})$$

Then we can work out how many seconds it will take to run up the stairs:

$$\text{Time to run up stairs} = 500 \text{ m} / 2.78 \text{ m/s}$$

$$\text{Time to run up stairs} = 180 \text{ seconds}$$

$$\text{Time to run up stairs} = 3 \text{ minutes} \quad (1 \text{ mark})$$

So it will take 3 minutes to run the stairs, leaving  $(6 - 3) = 3$  minutes to cycle down the road.

At an average downhill cycling speed of 50 km/hr, we can calculate how far Will would get in 3 minutes:

$$\text{Cycling distance} = \text{speed} \times \text{time}$$

$$\text{Cycling distance} = 50 \text{ km/hr} \times 3 \text{ minutes}$$

We need to convert everything into consistent units, I'm going to pick units of *metres* and *seconds*:

$$\text{Cycling distance} = 50 \text{ km/hr} \times 1000 / 3600 \times 3 \text{ minutes} \times 60 \text{ s/min} \quad (1 \text{ mark})$$

$$\text{Cycling distance} = 2500 \text{ metres} \quad (1 \text{ mark})$$

### Question 2

First let's convert the speed of 120 km/hr into m/s:

$$\text{Speed} = 120 \text{ km/hr} \times 1000 \text{ m/km} / 3600 \text{ s/hr}$$

$$\text{Speed} = 33.33 \text{ m/s} \quad (1 \text{ mark})$$

Then we can work out how far the wingsuit will travel sideways over 100 seconds:

$$\text{Wingsuit distance} = \text{speed} \times \text{time}$$

$$\text{Wingsuit distance} = 33.33 \times 100$$

$$\text{Wingsuit distance} = 3333 \text{ m} \quad (1 \text{ mark})$$

### Question 3

We can draw two similar triangles, one based on the wingsuit glide ratio, and one based on the wingsuit's horizontal and vertical velocity components:

This worksheet is based on events in the mathematical thriller *A Question of Will*. Get it now at:

**www.MathNovel.com**

Since the two triangles are similar, to calculate the vertical velocity of the wingsuit, all we need to do is divide the horizontal velocity by the glide slope ratio:

$$\text{Vertical wingsuit (falling) velocity} = 120 \text{ km/hr} / 2.5$$

$$\text{Vertical wingsuit (falling) velocity} = 48 \text{ km/hr} \quad (1 \text{ mark})$$

A quick search on the internet suggests that the terminal velocity of a free falling human with arms and legs outstretched (to create as much air resistance as possible) is approximately 200 km/hr. We can calculate the speed ratio between our wingsuit descent rate and that of a free falling human without a wingsuit:

$$\text{Speed ratio} = 200 / 48$$

$$\text{Speed ratio} = 4.17 \quad (1 \text{ mark})$$

So the wingsuit eventually slows the vertical rate of fall to about 4 times slower than that of a free falling human with arms and legs outstretched.

#### **Question 4**

To draw the graph of altitude versus time, we need to make sure we get a few points right:

1. At the moment of jumping, the vertical velocity is zero, and increases rapidly after this point in a quadratic manner **(1 mark)**
2. Sometime between 5 and 15 seconds the vertical velocity actually decreases as the wingsuit starts generating lift, and the horizontal velocity increases **(1 mark)**
3. After 15 seconds, the vertical and horizontal velocities of the wingsuit flyer are constant, which means the graph line should be a straight, downwards pointing line. **(1 mark)**
